Alberta's Environmental Science Program

The Chief Scientist has a legislated responsibility for developing and implementing Alberta's environmental science program for monitoring, evaluation and reporting on the condition of the environment in Alberta. The program seeks to meet the environmental information needs of multiple users in order to inform policy and decision-making processes. Two independent advisory panels, the Science Advisory Panel and the Indigenous Wisdom Advisory Panel, periodically review the integrity of the program and provide strategic advice on the respectful braiding of Indigenous Knowledge with conventional scientific knowledge.

Alberta's environmental science program is grounded in the principles of:

- *Openness and Transparency***.** Appropriate standards, procedures and methodologies are employed and findings are reported in an open, honest and accountable manner.
- *Credibility.* Quality in the data and information are upheld through a comprehensive Quality Assurance, Quality Control program that invokes peer review processes when needed.
- *Scientific Integrity.* Standards, professional values, and practices of the scientific community are adopted to produce objective and reproducible investigation.
- *Accessible Monitoring Data and Science.* Scientifically-informed decision making is enabled through the public reporting of monitoring data and scientific findings in a timely, accessible, unaltered and unfettered manner.
- *Respect.* A multiple evidence-based approach is valued to generate an improved understanding of the condition of the environment, achieved through the braiding of multiple knowledge systems, including Indigenous Knowledge, together with science.

Executive Summary

Background

This report was prepared by the Air and Watershed Stewardship Branch within the Resource Stewardship Division at Alberta Environment and Parks (AEP) to fulfill reporting requirements mandated by the South Saskatchewan Region Surface Water Quality Management Framework (SSR SWQMF; GOA 2014b), which supports the South Saskatchewan Regional Plan (SSRP; GOA 2014a).

The 2020-2021 report is the seventh annual report for the South Saskatchewan Region. Previous annual reports for the status of ambient environmental condition in the South Saskatchewan Region are accessible at: alberta.ca/south-saskatchewan-regional-planning.aspx. The Government of Alberta (GOA) determines reporting requirements for the SSRP and AEP has a responsibility for monitoring, evaluation and reporting under the Environmental Management Frameworks, including the SSR SWQMF. This report communicates any water quality triggers or limits that were exceeded from April 1, 2020 to March 31, 2021.

Methodology

The SSR SWQMF includes 15 primary indicators and six secondary indicators. In 2020-2021 (April 1 to March 31 inclusive), these water quality indicators were measured monthly at nine water quality monitoring stations. Using methodology described in the SSR SWQMF, the annual data for the 15 primary indicators were compared to the historical record to determine if the median and 90th percentile (peak) concentrations deviated in an undesirable direction from the historical median or peak trigger values. Values for primary indicators that deviated from historical triggers in an undesirable direction were statistically assessed for changes in the central tendency or peak concentration as per the SSR SWQMF: Statistical Methods Final Report (HDR 2011). 2020-2021 data for each primary and secondary indicator at each station were compared to historical data for both open water (April to October) and winter (November to March) seasons[1]. In addition, the 2020-2021 medians for primary indicators were compared to water quality limits as defined in the SSR SWQMF, and the 2020-2021 medians for secondary indicators were compared to provincial or federal water quality guidelines where available (GOA 2014b, GOA 2018).

2020-2021 (April 1 – March 31) Result Summary

For the following, exceedances were in both open water and winter seasons unless noted otherwise.

A statistically significant exceedance of the median trigger value was observed for:

- sulphate at Bow River at Carseland;
- nitrate at Bow River at Cluny;
- total dissolved solids at Bow River at Cochrane; and
- total nitrogen at Bow River at Cochrane (winter only).

A statistically significant exceedance of the peak trigger values was observed for:

- chloride at Bow River at Carseland, Bow River at Ronalane and Milk River at SH 880;
- sulphate at Bow River at Cochrane and Bow River at Carseland and Milk River at SH 880;
- *Escherichia coli* at South Saskatchewan River at Medicine Hat at Hwy 1 (winter only);

[1] Due to public health considerations during the COVID-19 pandemic, most of the sampling stations are missing samples in April and May. Please see “Monitoring Parameters” under “Methodology” for details.

- pH at Milk River at SH 880;
- specific conductance at Milk River at SH 880;
- Sodium Adsorption Ratio (SAR) at Milk River at SH 880; and
- total dissolved solids at Bow River at Cochrane, Bow River at Carseland and Milk River at SH 880.

There were no other median or peak trigger exceedances observed for any other stations or indicators.

Median total dissolved solids concentrations (winter only) and median *Escherichia coli* (open water only) at Milk River at SH 880 exceeded water quality limits (as defined in the SSR SWQMF). There were no other exceedances of surface water quality limits for primary indicators.

Although there were individual sample exceedances of mercury concentrations at Milk River at SH 880 and at the Bow River at Cluny in the open water season, 2020-21 median mercury concentrations did not exceed the applicable guideline value. There were no median guideline exceedances for the remaining secondary indicators.

South Saskatchewan Regional Plan

The South Saskatchewan Regional plan (SSRP) was developed by the Government of Alberta under the Land Use Framework (LUF; GOA 2008). The plan sets outcomes that describe what the Government of Alberta wants to accomplish at a regional level and is given legislative authority under the *Alberta Land Stewardship Act* (GOA 2009). The SSRP applies to the South Saskatchewan region (SSR), an area of approximately 83,764 square kilometers in size located in southern Alberta (Figure 1). For more information, see the SSRP publication (GOA 2014a).

The Air and Watershed Stewardship Branch within the Resource Stewardship Division at Alberta Environment and Parks (AEP) is responsible for monitoring, evaluation and reporting on the condition of the environment in the SSR. The 2020-2021 Status of Surface Water Quality for the South Saskatchewan Region report fulfills the annual reporting requirements mandated by the South Saskatchewan Region Surface Water Quality Management Framework for the mainstem Bow, Milk, Oldman and South Saskatchewan Rivers (SSR SWQMF; GOA 2014b), in support of the SSRP.

Methodology

Monitoring Stations

Water quality in the SSR is assessed based on data derived from monthly water quality sampling at nine Long-Term River Network (LTRN) stations within the SSR (Figure 2). The nine LTRN stations are located within four major river systems:

- **The Oldman River:** Oldman River at Brocket, Oldman River at Hwy 3 in Lethbridge and Oldman River at Hwy 36.
- **The Bow River:** Bow River at Cochrane, Bow River at Carseland, Bow River at Cluny and Bow River at Ronalane.
- **The South Saskatchewan River:** South Saskatchewan River at Medicine Hat at Hwy 1.
- **The Milk River:** Milk River at SH 880.

Additional details on the four major river basins and the nine LTRN stations are given in the SSR SWQMF (GOA 2014b).

Figure 1. Location of the seven Land-Use Framework Regions in Alberta. The South Saskatchewan Region is shaded green.

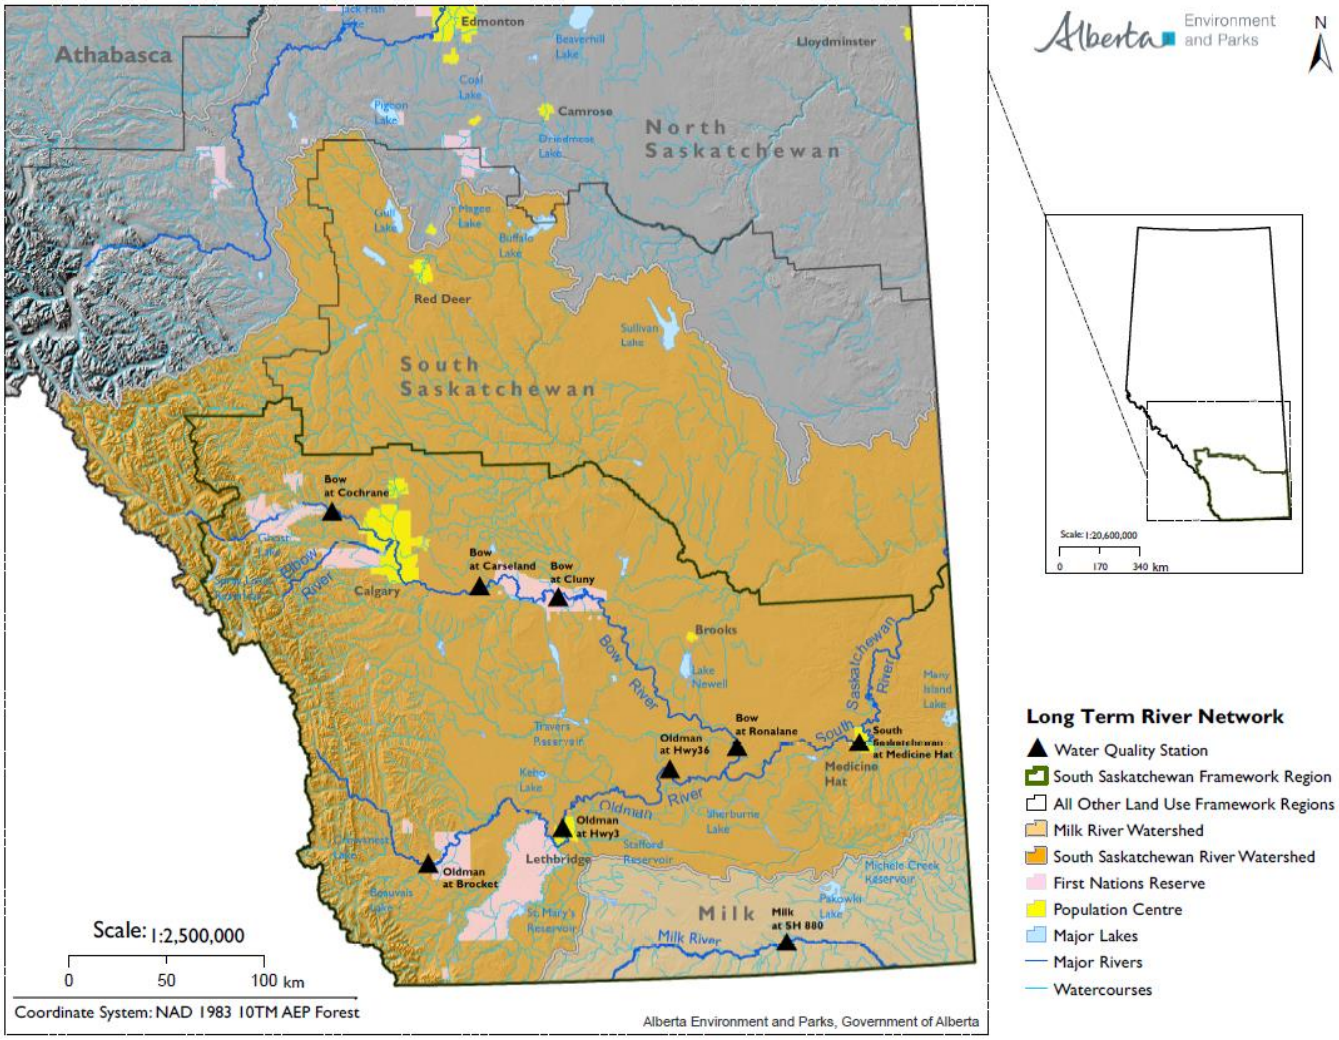

Figure 2. Location of Long Term River Network water quality stations used in the SSR SWQMF.

Monitoring Parameters

Annual data used in the 2020-2021 report were taken from monthly water quality samples at the nine LTRN stations within the SSR, taken between April 2020 and March 2021. Twenty-one water quality parameters, including 15 primary indicators (Table 1) and six secondary indicators (Table 2), were chosen as indicators in the framework. Rationale for indicator selection is given in the SSR SWQMF (GOA 2014b). Sample collection, data verification and analyses follow recognized standards and protocols established by AEP for consistent sample collection and processing across the Province (AENV 2006).

Due to public health considerations during the COVID-19 pandemic, samples were not collected at any LTRN station in April 2020. In May 2020, only one LTRN station in the SSR was sampled (Milk River at SH 880). Monthly water quality sampling recommenced for the full network from June 2020 and continued throughout the remainder of the monitoring period. The sampling resulted in 11 compliance samples for the Milk River at SH 880 site and 10 compliance samples for the other LTRN stations.

Statistical Analysis

Median (50th percentile) and peak (90th percentile) triggers were calculated from historical datasets (1999-2009, with some exceptions; see GOA 2014b), and separately for two different seasons: the open-water season (April to October) and the winter season (November to March). This seasonal split is to address the difference in seasonal temperature and precipitation patterns as they affect water quality measurements. For primary indicators, seasonal median and peak concentrations calculated from the 2020-2021 data were first compared to these historical triggers to determine if there was deviation in an undesirable direction from the historical trigger values. With the exception of pH, an undesirable direction is a value greater than the trigger. For pH, values below or above the trigger could be potentially impactful (i.e., increased acidity or increased alkalinity). Seasonal median or peak concentrations (calculated from 2020-2021 data) that crossed their respective historical trigger values in an undesirable direction were then assessed for statistical significance to determine if there was a (median or peak) trigger exceedance.

A median trigger exceedance is defined as a statistically significant shift in the central tendency of the 2020-2021 data for open water and winter seasons, relative to a corresponding upper prediction limit (UPL) calculated from the historical record (HDR 2011). A peak trigger exceedance was reported when the frequency of observations in the 2020-2021 data exceeding an UPL calculated from the historical record was higher than an expected frequency. A peak trigger exceedance also represents a statistically significant shift in the frequency of extreme values in the 2020-2021 data. Details of the statistical analyses used to determine a median or peak trigger exceedance are in Appendix A. Identification of median and peak exceedances are intended to act as an early warning system of potential changes in surface water quality and a signal to do further analyses (preliminary assessment) to determine the need for further investigation.

Water quality limits for primary and secondary indicators were derived from provincial and federal water quality guidelines (GOA 2014b). A surface water quality limit is exceeded if the seasonal 2020-2021 median for a given indicator exceeded the surface water quality limit for that indicator. For water quality indicators that are affected by toxicity modifying factors (i.e., total ammonia and sulphate), individual limits were calculated for each sample in the compliance year using guideline equations (GOA 2018). Individual concentrations from the compliance data were then compared against corresponding calculated limits. If greater than 50% of all months exceeded their calculated limits for a specific parameter at a specific site within a season, this was identified as a limit exceedance.

Historically, AEP replaced any censored data of a given parameter (i.e., observations measured below the method detection limit) with one-half of the detection limit value. This practice was adopted for this report with the calculation of the historical triggers, as well as with the annual compliance dataset. Statistical methods used in this report are described in the SSR SWQMF: Statistical Methods Final Report (HDR 2011), *Unified Guidance* (USEPA 2009) and Smith et al. (2001). Additional details on the analytical and statistical methods are provided in Appendix A and the SSR SWQMF (GOA 2014b). All statistical assessments were performed using R statistical software (Millard 2013, R Development Core Team 2020).

Results

Exceedances of Water Quality Triggers

In 2020-2021, statistically significant median and peak trigger exceedances were observed at six stations for nine primary indicators. Unless otherwise noted, these exceedances are for combined open water and winter season datasets.

A statistically significant exceedance of the median trigger value was observed for:

- sulphate at Bow River at Carseland;
- nitrate at Bow River at Cluny;
- total dissolved solids at Bow River at Cochrane; and
- total nitrogen at Bow River at Cochrane (winter only).

A statistically significant exceedance of the peak trigger values was observed for:

- chloride at Bow River at Carseland, Bow River at Ronalane and Milk River at SH 880;
- sulphate at Bow River at Cochrane and Bow River at Carseland and Milk River at SH 880;
- *Escherichia coli* at South Saskatchewan River at Medicine Hat at Hwy 1 (winter only);
- pH at Milk River at SH 880;
- specific conductance at Milk River at SH 880;
- Sodium Adsorption Ratio (SAR) at Milk River at SH 880; and
- total dissolved solids at Bow River at Cochrane, Bow River at Carseland and Milk River at SH 880.

There were no other median or peak trigger exceedances observed for any other stations or indicators. Summary statistics, including the annual and historical medians (50th percentile) and peaks (90th percentile) are presented in Appendix B.

Table 3. Median and peak (90th percentile) values for primary indicators exhibiting a statistically significant trigger exceedance (shaded in blue) in the SSR during 2020-2021. Calculation results leading to identification of the statistically significant trigger exceedances are listed in Table 4. An asterisk for the compliance period indicates that the statistically significant exceedances were calculated with aggregate (open + winter) data.

Station	Indicator	Period	Season	Median	90th Percentile	n

Exceedances of Water Quality Limits

Median total dissolved solids concentrations (winter only; 510 mg/L) and median *Escherichia coli* (open water season only; 136 cfu per 100 mL) at Milk River at SH 880 exceeded water quality limits (as defined in the SSR SWQMF). There were no other exceedances of surface water quality limits for primary indicators.

Table 5. List of surface water quality limits for primary indicators. Limit values were taken from the SSR SWQMF (GOA 2014b).

Primary Indicator	Units	Surface Water Quality Limit
Total Ammonia	mg/L	Varies with pH and temperature[A]
Chloride	mg/L	100
Nitrate	mg/L	3.0
Sulphate	mg/L	Varies with hardness[A]
Sodium Adsorption Ratio (SAR)	rel units	5
Specific Conductance	µS/cm	1000
Total Dissolved Solids	mg/L	500
pH	pH units	<6.5 or >9.0
Escherichia coli	cfu per 100 mL	100

[A] Calculations are given in Environmental Quality Guidelines for Alberta Surface Waters (GOA 2014c).

Exceedances of Secondary Indicators

Although there were individual chronic guideline exceedances of mercury concentrations at Milk River at SH 880 and at the Bow River at Cluny in the open water season, median mercury concentrations did not exceed the applicable guideline value (GOA 2018). There were no median guideline exceedances for the remaining secondary indicators (GOA 2018). Summary statistics for all secondary indicators are provided in Appendix B. Note that summary statistics shown for secondary indicators are for information purposes only as there are no triggers or limits assigned to these indicators.

Table 6. List of guideline values for secondary indicators. Guideline values were taken from the Environmental Quality Guidelines for Alberta Surface Waters (GOA 2018).

Secondary Indicator	Unit	Protection of Aquatic Life	Protection of Agricultural Water Use (Irrigation)	Protection of Agricultural Water Use (Livestock Water)
Total Mercury	ug/L	(chronic) 0.005 (acute) 0.013	---	3
Total Selenium	ug/L	(guideline) 2 (alert) 1	---	50
2,4-Dichlorophenoxyacetic acid (2,4-D)	ug/L	(chronic) 4	---	See ”Phenoxy herbicides”
Dicamba	ug/L	(chronic) 10	0.008	122
Methylchlorophenoxyacetic acid (MCPA)	ug/L	(chronic) 2.6	(continuous use) 20 (intermittent use) 50	See ”Phenoxy herbicides”
Mecoprop (MCPP)	ug/L	(chronic) 13 (acute) 10,000	---	See ”Phenoxy herbicides”
Phenoxy herbicides (sum of all phenoxy herbicides including 2,4-D, MCPP, MCPA)	ug/L	See individual indicators above	See individual indicators above	100

Analytical and Statistical Methods Used to Assess Trigger and Limit Exceedances

The South Saskatchewan Region Surface Water Quality Management Framework (SSR SWQMF) established median and 90th percentile triggers for 15 primary indicators and identifies six secondary indicators, for which there were not enough data of sufficient length and/or level of analytical detection to facilitate the quantification of robust trigger values (GOA 2014b). Water samples for general parameters were analyzed by Bureau Veritas. *Escherichia coli* was analysed by ProvLab Alberta. Mercury was analysed by University of Alberta Biogeochemical Analytical Service Laboratory. Selenium and pesticides were analysed by InnoTech Alberta. All statistical analyses and plots were conducted using packages *EnvStats* (v2.3.1; Millard 2013), *lawstat* (v3.4; Gastwirth et al. 2020), *lmtest* (v0.9.37; Zeileis and Hothorn 2002), *MASS* (v7.3.51.5; Venables and Ripley 2002), and *outliers* (v0.14; Komsta 2011) in R version 4.0.0. (R Development Core Team 2020). Analyses used were based on recommendations made in the *South Saskatchewan Regional Plan Surface Water Quality Management Framework: Statistical Methods Final Report* (HDR 2011).

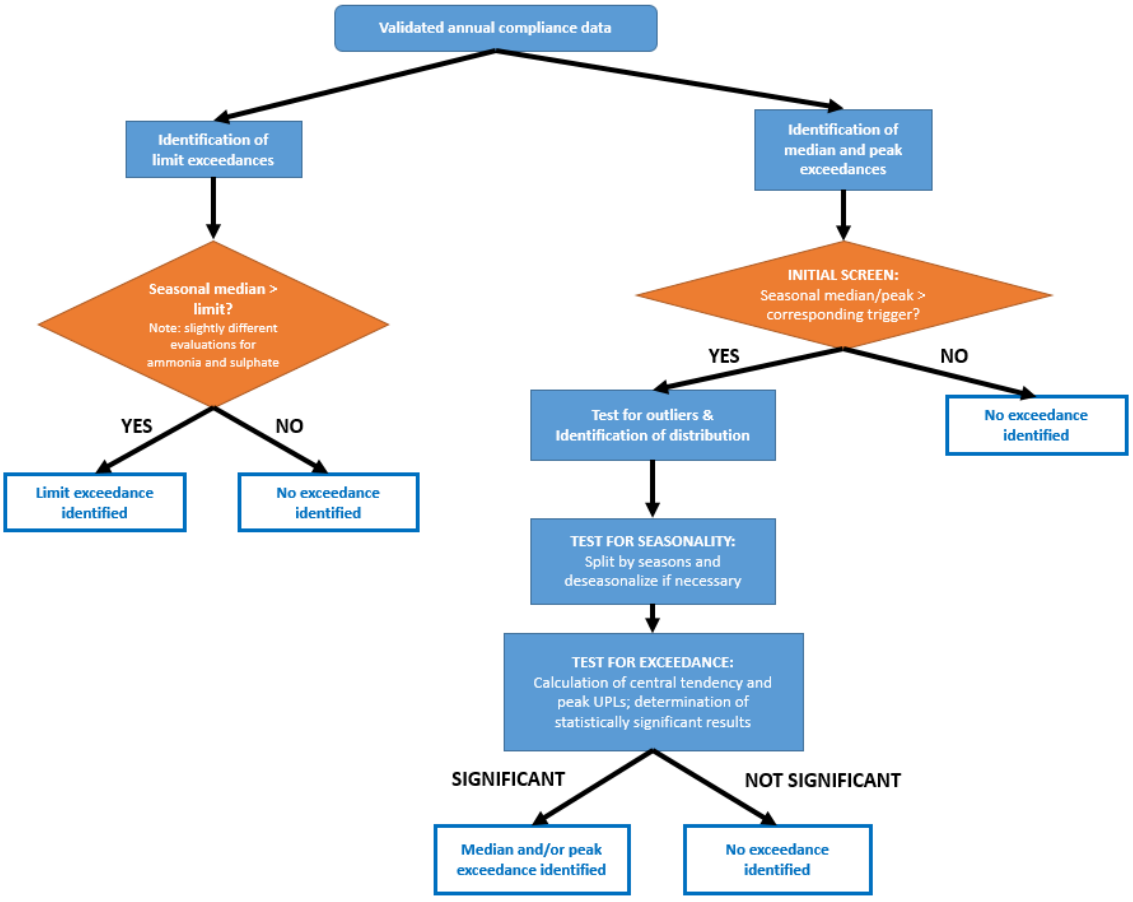

Figure A-1. Overview flowchart of the statistical steps taken in SSR SWQMF.

Preliminary Data Screening

All water quality data used in the assessment were from the Long-Term River Network (LTRN) stations in the South Saskatchewan River Basin. The historical dataset (used for trigger development and comparisons against annual compliance data) included data from April 1999 to March 2009 (actual time range dependent on parameter; see GOA 2014b).The annual compliance data for a given year (e.g., 2020-2021) includes data from the beginning of April to the end of next March (e.g., April 1, 2020 to March 31, 2021). Any data points below the method detection limit (MDL) were substituted with a value of ½ MDL.

Each year is divided into two seasons: open water (April to October) and winter (November to March). Seasonal median and 90th percentile (peak) triggers were calculated for each water quality indicator using the historical dataset, to reproduce values listed in the SSR SWQMF (GOA 2014b). Seasonal median and 90th percentile concentrations are then calculated for each indicator in the annual compliance dataset. For each indicator and season at each station, the compliance median and peak value were compared to its respective historical trigger. If the compliance value exceeded the trigger value, the indicator was flagged for further statistical analyses to determine if there was a significant deviation from historical triggers in an undesired direction. Note that for pH, when compliance data were either above or below the trigger values at a given site, further statistical analyses were undertaken. This was to account for the fact that both lower than historic or higher than historic pH values could be considered undesirable. Seasonal median compliance values were also compared to surface water quality limits (based on provincial and federal guidelines and defined in SSR SWQMF; GOA 2014b), and any exceedances of the limits by the calculated medians were reported (Figure A-1 and A-2).

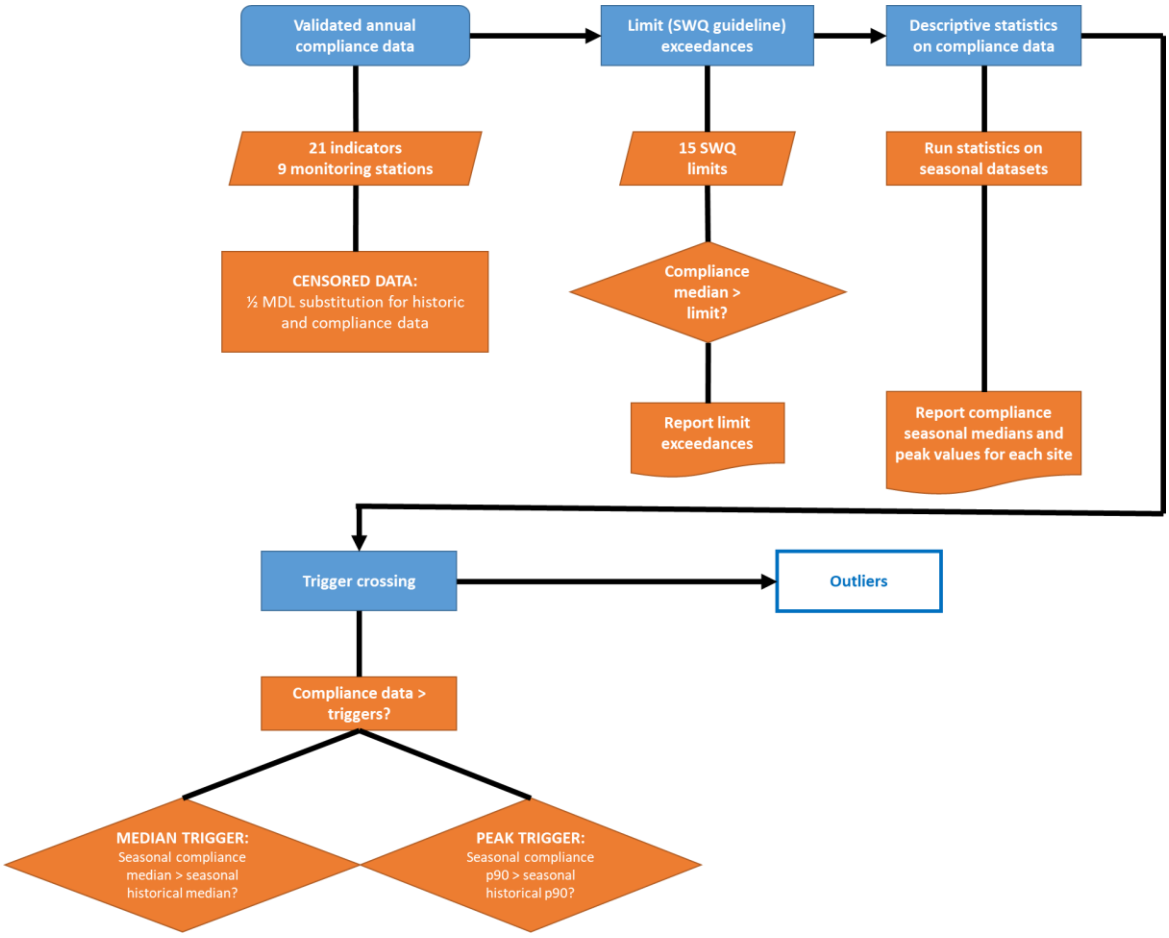

Figure A-2. Flowchart of preliminary data screening steps.

Outlier and Distribution Testing

Regardless of whether the open water season or the winter season trigger was exceeded in a particular parameter, a seasonal aggregate (open water and winter combined) dataset was first statistically analysed for significance. Outliers were detected using Rosner's outlier test. Distribution of the temporal aggregate data (historical and annual compliance data combined) was preliminarily assessed using Q-Q plots and goodness-of-fit (GoF) tests based on a ProUCL algorithm, which uses the Lilliefors test for datasets with n>50 (function *EnvStats::distChoose()*) Figure A-3. A value of 0.001 was added to individual concentrations to account for cases of 0 CFU/100 mL for *Escherichia coli* concentrations, which may generate issues with the GoF procedure. This addition was done for all runs for consistency. For these tests, significance level was set at $\alpha = 0.01$.

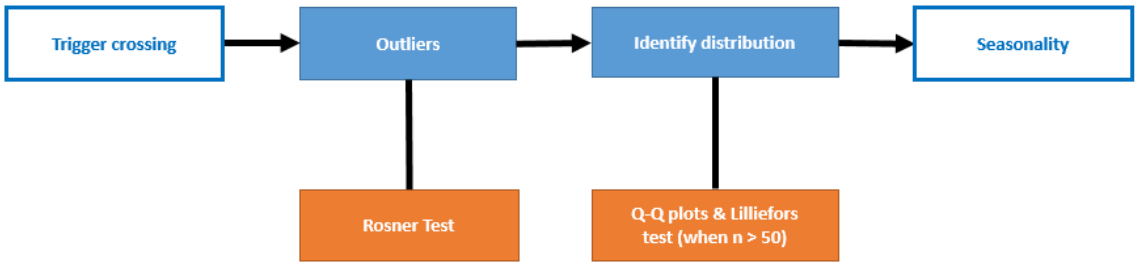

Figure A-3. Flowchart of outlier and distribution testing steps.

Seasonality

HDR (2011) recommended testing the seasonal aggregate data (historical and annual compliance data) for seasonality, and if detected, the data was deseasonalized with a simple correction method. With this approach, for each month, the monthly mean was subtracted from all values in that month and then the overall mean across all months was added back to each individual value. Residuals were calculated using the function *stats::lm()* to fit a regression line. Distribution of residuals between months was evaluated using the Shapiro-Wilk test ($\alpha = 0.01$), and variances analysed with Levene's test ($\alpha = 0.01$). Differences between months were evaluated using a one-way ANOVA ($\alpha = 0.05$) if residuals were normal or log-normal, and the monthly data showed equal variance. Otherwise, it was evaluated using the non-parametric Kruskal-Wallis test ($\alpha = 0.05$). If seasonality was significant, the dataset was deseasonalized.

In addition to temporal correlation between monthly data, some values may exhibit a dependence on the water state (open water vs. winter). As such, HDR (2011) recommends a final preprocessing check to determine if the difference between the two groups is statistically significant. If the results indicate that there is no significant seasonality in the data, the analysis proceeds with the combined dataset (open water and winter data). In the event that the seasonality is significant, the data are split into their respective groups (i.e. open water and winter data) and exceedance tests are conducted on the separate groups. The distribution of residuals between subgroups was evaluated using the Shapiro-Wilk test ($\alpha = 0.01$).Then differences between subgroups were evaluated using a one-way ANOVA ($\alpha = 0.05$; if residuals were normal or log-normal and variance was equal) or a Kruskal-Wallis rank sum test ($\alpha = 0.05$). If a significant difference between subgroups is indicated, then data grouping is required, the dataset is separated into open water and winter data, and each group re-assessed for outliers, distribution and seasonality (Figure A-4).

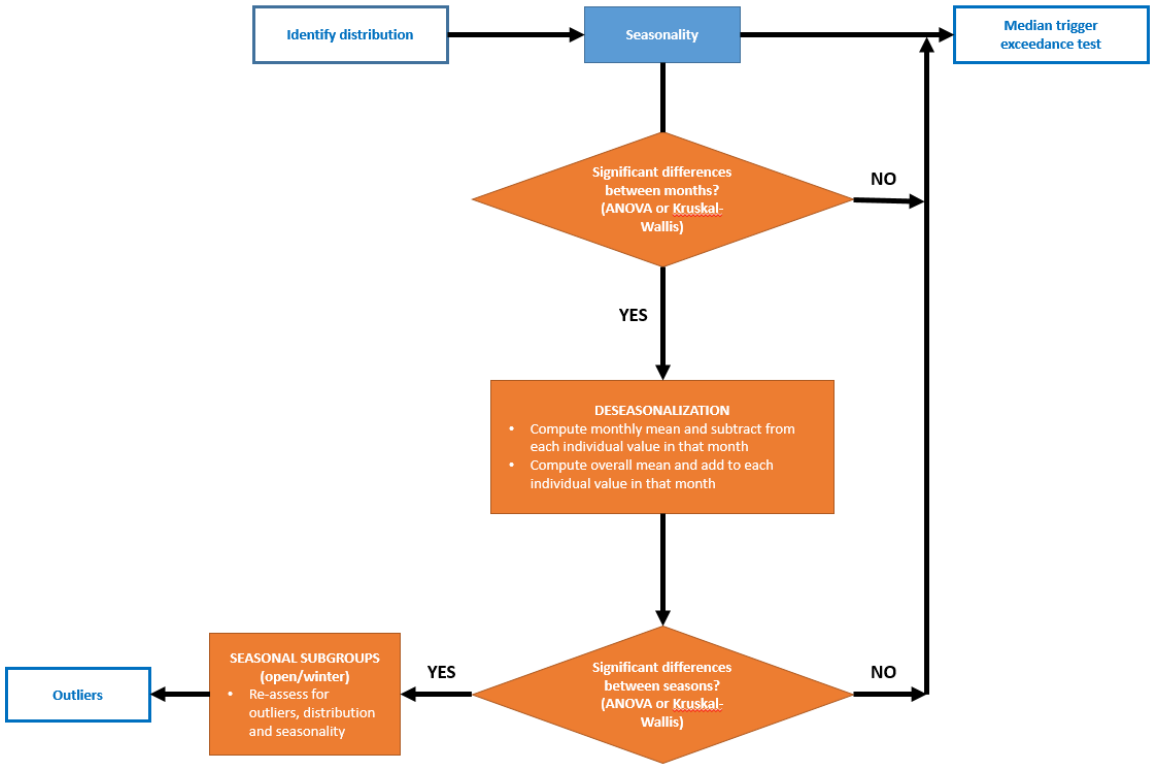

Figure A-4. Flowchart of seasonality testing steps.

Trigger Exceedances

HDR (2011) recommends the use of upper prediction limits (UPLs) over the use of median, 90th/95th percentiles or upper confidence limits for establishing baseline limits against which future observations would be tested. UPLs are not directly comparable to empirical percentile values; the 90th percentile UPL represents “the value above which there is only a [10]% likelihood that new or future observations will occur” (HDR 2011, p. 31).

To test whether the historical data and compliance data are from the same distribution, a Kolmogorov-Smirnov test was used. If both datasets were from a normal or log-normal distribution, the parametric UPL calculations were used; if both datasets were from a non-normal distribution, the non-parametric UPL calculations were used. If the two datasets did not come from the same distribution, the non-parametric UPL calculations were used. Only historical data was used in the calculation of UPLs (Figure A-5).

Median Trigger Exceedances

To evaluate exceedances of the median trigger, an UPL was calculated from the historic dataset using *EnvStats::predIntNorm()*, *EnvStats::predIntLNorm()* or *EnvStats::predIntNpar()*, for normal, log-normal and non-parametric distributions respectively. The UPL was compared to the compliance mean (mean of compliance data) if the normal or log-normal UPL was used. If the non-parametric UPL was used, however, the median of the three most recent compliance observations was used instead (HDR 2011, USEPA 2009). If the compliance mean/median (dependent on distribution) was greater than the UPL limit, a compliance median trigger exceedance occurred.

Peak Trigger Exceedances

For evaluating peak trigger exceedances in normally or log-normally distributed data, a UPL was calculated as the prediction interval for the next 12 observations using the historic dataset. This UPL was compared to each individual compliance data point. For normal data, *EnvStats::predIntNorm()* and *EnvStats::predIntLNorm()* was used for this calculation. For non-normal data, the *EnvStats::predIntNpar()* calculation, which corresponds to a percentile limit, was used to calculate an UPL for comparison against individual compliance data points in non-parametric data.

The percentage of compliance data points that exceed the UPL was recorded, and a binomial test was applied to the number of exceedances. If the number of individual exceedances was greater than the acceptable number of violations (10% natural violations), a compliance peak trigger exceedance has occurred.

Limit Exceedances

Limit exceedances were determined by comparing the seasonal compliance median concentrations to the limit values defined in SSR SWQMF (GOA 2014b). If the seasonal median concentration calculated from the current year exceeded the limit value for a specific parameter at a specific site, this was identified as a limit exceedance. For water quality indicators that are affected by toxicity modifying factors (i.e., total ammonia and sulphate), individual limits were calculated for each sample in the compliance year using guideline equations (GOA 2018). Individual concentrations from the compliance data were then compared against corresponding calculated limits. If greater than 50% of all months exceeded their calculated limits for a specific parameter at a specific site within a season, this was identified as a limit exceedance.

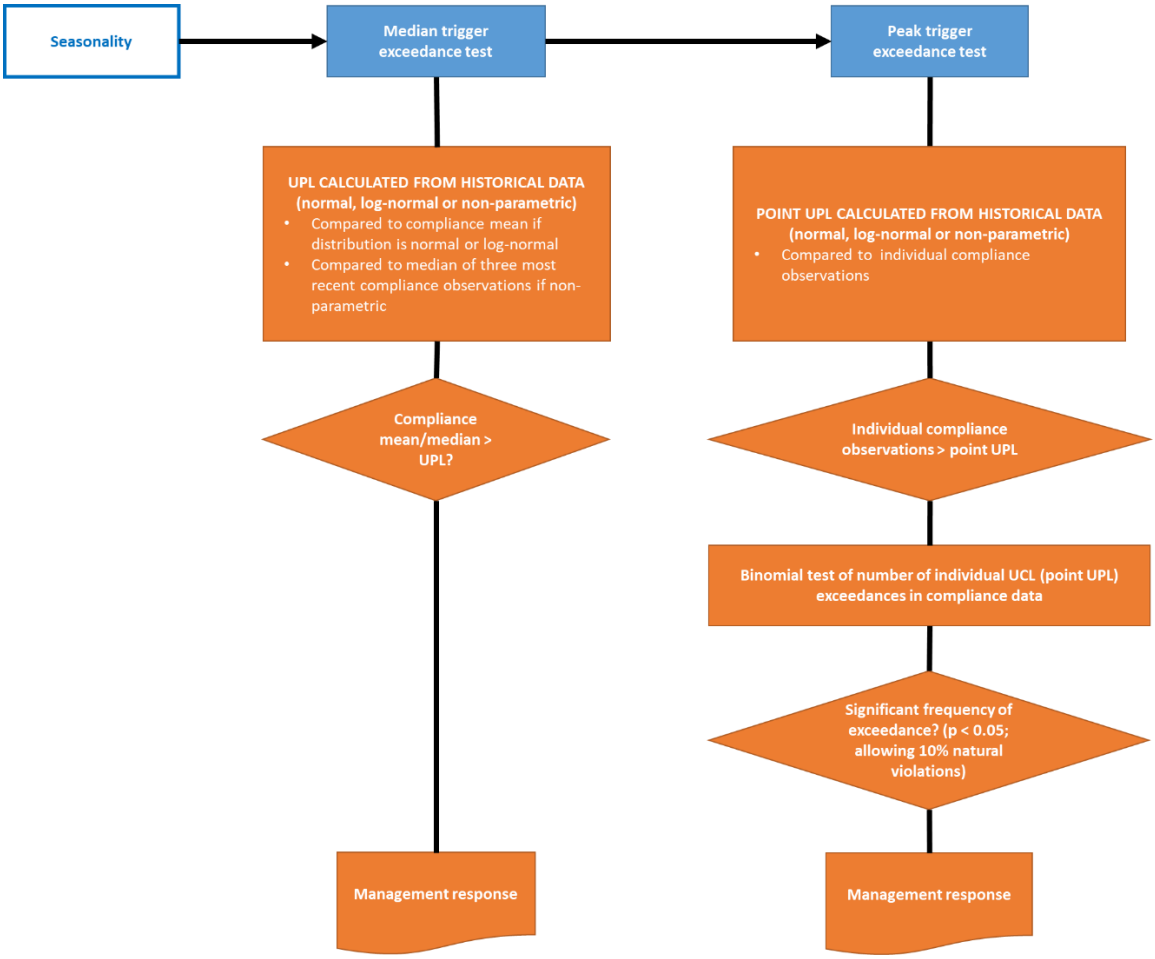

Figure A-5. Flowchart of exceedance testing steps.

Appendix C

Statistical Summary, LTRN Station Information and Boxplots

Table C-1. Results of the statistical assessment of the 2020-2021 compliance values against the Framework triggers for sites on the Oldman River**.** The surface water quality parameters with concentrations that had statistically significant test results are highlighted. Normal and log-normal distributions used parametric UPL calculations, while non-normal distributions used non-parametric UPL calculations. Central tendency UPL trigger exceedances were reported (e.g. FAIL) when the compliance mean/median values exceeded the central tendency UPL. Peak UPL trigger exceedances (e.g. FAIL) were reported when there was a significant number of individual values exceeding the peak UPL determined with the binomial test.

Indicator	Units	Distribution	Deseasonal-ized? (i.e., difference between months)	Separated by Seasons	Season (O=open; W=winter)	Compliance Mean/ Median	Central Tendency UPL	Central Tendency UPL Pass/Fail	Peak UPL	No. of Individual Exceedance	Peak UPL Pass/Fail

Table C-3. Results of the statistical assessment of the 2020-2021 compliance values against the Framework triggers for sites on the South Saskatchewan and the Milk Rivers. The surface water quality parameters with concentrations that had statistically significant test results are highlighted. Normal and log-normal distributions used parametric UPL calculations, while non-normal distributions used non-parametric UPL calculations. Central tendency UPL trigger exceedances were reported (e.g. FAIL) when the the compliance mean/median values exceeded the central tendency UPL. Peak UPL trigger exceedances (e.g. FAIL) were reported when there was a significant number of individual values exceeding the peak UPL determined with the binomial test.

Indicator	Units	Distribution	Deseasonal-ized? (i.e., difference between months)	Separated by Seasons	Season (O=open; W=winter)	Central Tendency Mean/ Median	Central Tendency UPL	Central Tendency UPL Pass/Fail	Peak UPL	No. of Individual Exceedance	Peak UPL Pass/Fail
