Background

“How are the fish in my lake doing?” We need this answer to set appropriate fishing regulations, to understand and correct any problems with fish habitat, and to guard against invasive species. A healthy fish population and fish community means we can all enjoy the benefits of sustainable fisheries and healthy ecosystems. A standard method of assessing the status of fish populations is necessary to allow comparisons of fish sustainability across the years at a lake, and to compare to other lakes. In Alberta, we use an accepted standard of index netting for lake fisheries assessment. This method provides the necessary data on fish abundance, biological data (such as age and sex), and species diversity to assess sustainability.

Fall Index Netting (FIN)

Alberta Environment and Parks monitor Walleye and Northern Pike populations using standardized index netting (Morgan, 2002). Fall index netting occurs during late summer and fall when water temperatures are 10-15 °C. Standardized multi-mesh gill nets are set at random locations between 2 and 15 metres deep, set for 21-27 hours (i.e., a net-night), and then reset in new random locations. Information from Yellow Perch, Lake Whitefish, Burbot, minnow, and sucker species are also collected. The information collected from each fish includes length, weight, age, gender, and maturity. After sampling, if fish are appropriate for human consumption, Alberta biologists provide the fish to local Indigenous peoples or to persons on approved subsistence lists. Typically, a tiny proportion of the lake’s fish population (usually less than 1 or 2%) are killed in this sampling.

How is this information used?

Catch rates (i.e., number of fish captured per net-night) of Walleye and Northern Pike are an index of the populations’ abundance, with higher catch rates meaning there are more fish in the lake. The abundance of adult fish is compared to the standardized thresholds for 5 broad categories of risk to the long-term sustainability of the fish population, with higher densities of fish having lower risk (Table 1). The sizes and age of fish also tell us if problems with overharvest (e.g., too few fish living to old age) or habitat (e.g., poor spawning success) are a concern. Biologists use this information, as well as a variety of data on water quality, access, development, and habitat threats as part of Alberta’s Fish Sustainability Index (FSI).

The management goal for most Alberta fisheries is long-term sustainability, shown by the red lines on the graphs below.

Achieving this goal uses the netting data and the FSI to determine the most appropriate sport fishing regulations for a lake. This landscape-level assessment allows for consistent, broad temporal comparisons of fish sustainability and status. For more information please see Alberta’s FIN and FSI websites,

Table 1 – Alberta’s Fish Sustainability Index risk thresholds for Walleye and Pike using the standardized Fall Index Net (FIN) method. Note: Thresholds align with species management frameworks.

Results of the 2013 FIN at McGregor Lake

McGregor Lake (4731 ha) is located 100 km southeast of the city of Calgary. From September 24-26, 2013, sixteen gill nets captured 90 Lake Whitefish, 1 Longnose Sucker, 22 Northern Pike, 14 White Suckers, 251 Walleye, and 7 Yellow Perch, from McGregor Lake.

Walleye

The mean catch rate of Walleyes was 15.7/net-night. The catch rates of mature (Figure 1) and immature Walleye were 10.4/net-night and 5.3/net-night, respectively. The corresponding FSI score for the current mature density of Walleye was assessed at high risk.

The length distribution shows very low and unstable recruitment, moderate abundance of fish 390 to 660 mm (Figure 2). As McGregor Lake is a irrigation reservoir, variable water levels (i.e., spawning habitat) may contribute to unstable recruitment.

The 2013 FIN sample represented approximately 0.6% of the estimated Walleye population size.
Figure 1 – The FIN catch rate of mature Walleyes from McGregor Lake, 2013. Dashed line is the mean likelihood catch rate (10.4/fish/net-night), with net individual data as hollow circles (n=16 nets).

Figure 2 – FIN sample of showing size of Walleyes from McGregor Lake, 2013. The red line indicates the average length distribution of Walleye from 5 Alberta lakes supporting long-term sustainable harvests of Walleye.

Northern Pike
The mean catch rate of mature Northern pike was 1.0/net-night (Figure 3). The corresponding FSI score for the mature density of Northern Pike was assessed at very high risk.

The length distribution shows extremely low recruitment, and low abundance of all size-classes of Northern Pike (Figure 4). The irrigation reservoir likely sees variable water levels and therefore variable spawning and littoral habitats that limit Northern Pike.

The 2013 FIN sample represented approximately 0.1% of the estimated Northern Pike population size.

Summary
Since the 2008 FIN on McGregor lake, the FSI status of the Walleye population has decreased from moderate risk to high risk. Dependant on the management objective, continued strict conservation-based management is necessary to maintain this fishery.

Since 2008 FIN on McGregor Lake, the FSI status of Northern Pike has remained at very high risk and, dependant on the management objective, strict conservation-based management is necessary to maintain this reservoir population.
