Background

“How are the fish in my lake doing?” We need this answer to set appropriate fishing regulations, to understand and correct any problems with fish habitat, and to guard against invasive species. A healthy fish population and fish community means we can all enjoy the benefits of sustainable fisheries and healthy ecosystems. A standard method of assessing the status of fish populations is necessary to allow comparisons of fish sustainability across the years at a lake, and to compare to other lakes. In Alberta, we use an accepted standard of index netting for lake fisheries assessment. This method provides the necessary data on fish abundance, biological data (such as age and sex), and species diversity to assess sustainability.

Fall Index Netting (FIN)

Alberta Environment and Parks monitor Walleye and Northern Pike populations using standardized index netting (Morgan, 2002). Fall index netting occurs during late summer and fall when water temperatures are 10-15 °C. Standardized multi-mesh gill nets are set at random locations between 2 and 15 metres deep, set for 21-27 hours (i.e., a net-night), and then reset in new random locations. At Blackett Lake in 2015, a half-length variation of the standard index net was used, balancing precision of the catch rates with reduced sampling effort. Information from Yellow Perch, Lake Whitefish, Burbot, minnow, and sucker species are also collected. The information collected from each fish includes length, weight, age, gender, and maturity. After sampling, if fish are appropriate for human consumption, Alberta biologists provide the fish to local Indigenous peoples or to persons on approved subsistence lists. Typically, a tiny proportion of the lake’s fish population (usually less than 1 or 2%) are killed in this sampling.

How is this information used?

Catch rates (i.e., number of fish captured per net-night) of Walleye and Northern Pike are an index of the populations’ abundance, with higher catch rates meaning there are more fish in the lake. The abundance of adult fish is compared to the standardized thresholds for 5 broad categories of risk to the long-term sustainability of the fish population, with higher densities of fish having lower risk (Table 1). The sizes and age of fish also tell us if problems with overharvest (e.g., too few fish living to old age) or habitat (e.g., poor spawning success) are a concern. Biologists use this information, as well as a variety of data on water quality, access, development, and habitat threats as part of Alberta’s Fish Sustainability Index (FSI).

The management objective for most Alberta fisheries is long-term sustainability, shown by the red lines on the graphs below. Achieving this objective uses the netting data and the FSI to determine the most appropriate sport fishing regulations for a lake. This landscape-level assessment allows for consistent, broad temporal comparisons of fish sustainability and status. For more information please see Alberta’s FIN and FSI websites,

Results of the 2015 FIN at Blackett Lake

Blackett Lake (783 ha) is located approximately 26 km east from the town of Lac La Biche. This lake is directly connected to two other lakes (Kinnaird, Jackson) and the walleye and pike are managed as combined populations. From September 28 to October 1, 2015, twelve ½ length nets captured 24 Cisco, 52 Northern Pike, 97 Walleye, and 73 Yellow Perch.

Walleye

The mean catch rate of Walleyes was 8.1/½ net-night. The catch rates of mature (Figure 1) and immature Walleye were 7.8/½ net-night and 0.3/½ net-night, respectively. The corresponding FSI score for the current mature density of Walleye was assessed at moderate risk.

The length distribution shows abundant Walleye larger than 430 mm, however, with very poor recruitment (Figure 2). Poor recruitment could be a result of habitat issues (e.g., low water levels) or past overfishing.
**Northern Pike**

The mean catch rate of mature Northern Pike was 3.7/½ net-night (Figure 3). The corresponding FSI score for the current mature density of Northern Pike was assessed at **high risk**.

The length distribution shows a severe truncation of fish larger than 530 mm and relatively stable recruitment of smaller fish (Figure 4), indicative of growth overfishing.

The 2015 FIN sample represented approximately 0.3% of the estimated mature Northern Pike population size.

**Summary**

Since the FINs on Blackett Lake in 2005 and 2010, the density of mature Walleye has decreased from a FSI status of **low** risk to a status of **moderate risk**, primarily because of recruitment failures.

The decrease of Blackett Lake’s Walleye population may require careful conservation and monitoring.

Since the FINs in 2005 and 2010, the density of mature Northern Pike in Blackett Lake has remained at a FSI status of **high risk**. With the truncation of the large fish and stable recruitment, conservation-focused management may be necessary to improve the quality of this fishery.
